

How to Resolve Errors with Custom MX Records and Sending Email From VPS

If domain.com is hosted on a VPS.net with Cpanel and has custom MX records (for example, using Google Apps), then emails sent by PHP scripts or emails sent by VPS itself to @domain.com will not be delivered.

This happens because domain.com exists in /etc/localdomains.

In order to fix the issue and make Exim resolve real MX records, you can do the following:

Remove domain.com from

```
/etc/localdo  
mains
```

and

Add domain.com to

```
/etc/remotedo  
mains
```

in your cPanel/WHM server.
